Selecting Reagents for Multicolor Flow Cytometry

From HotLines Platinum Edition, Fall 2006

By Holden Maecker and Joe Trotter

The availability of flow cytometers capable of detecting 6, 8, or more colors has spurred the discovery of new fluorochromes and the development of antibody conjugates. However, the complexities of choosing antibody combinations are such that simply using a random combination of fluorochromes for a particular set of antibody specificities is unlikely to provide optimal results. On the other hand, with a bit of forethought, one can usually avoid many rounds of trial and error. The goal of this article is to provide some simple guidelines to aid in the selection of reagent panels for multicolor flow cytometry, which should result in more successes than failures.

The basics: Know your instrument

Reagent selection starts with your instrument configuration. The lasers and detectors that you have available dictate whether or not you can excite a given fluorochrome, and whether or not you have enough detectors to read out a given combination of fluorochromes. The design of the optical system also impacts the efficiency with which particular dyes are detected, as do the instrument settings, including PMT voltages (see the BD Application Note, *Establishing Optimum Baseline PMT Gains to Maximize Resolution on BD Biosciences Digital Flow Cytometers* at **bdbiosciences.com/baselineoptimization**). Finally, the choice of optical filters that are used with each detector greatly influences the brightness of one fluorochrome versus another. One can think of filter selection as a give-and-take process: using a wider bandpass filter can increase the ability to detect a given fluorochrome, but may also increase the amount of spillover detected in that detector from other neighboring fluorochromes. A good way to visualize these effects is by virtual testing of filter combinations using a web tool such as the fluorescence spectrum viewer at **bdbiosciences.com/spectra**. Here you can get an idea of predicted spillovers* for particular fluorochromes and filter combinations.

* The predicted spillovers are normalized percentages of omitted fluorescence, and may not necessarily correspond to the percentage used for compensation due to the effects of varying detector gains.

Fluorochromes: Go for the bright

Given the many differences in instrument configuration, it is impossible to universally state the "best" fluorochromes to use in combinations of 6, 8, or more colors. However, if one considers a particular cytometer such as the BD™ LSR II instrument, it is possible to rank available dyes according to their brightness on that instrument (when configured with a specified set of lasers and filters). But how exactly do we define and measure brightness? A good definition of brightness should probably start with *resolution sensitivity*, the ability to discriminate a dim positive signal from background. Background in a particular detector is influenced by electronic noise, cell autofluorescence, and spillover from other detectors. To the extent that these factors introduce noise, they also increase the width (or standard deviation, SD) of a negative fluorescence peak (see **Figure 1**). As such, a good measure of resolution sensitivity is the stain index,[1] defined as D/W, where D is the difference between means of a positive and negative peak, and W is equal to 2 SD of the negative peak.

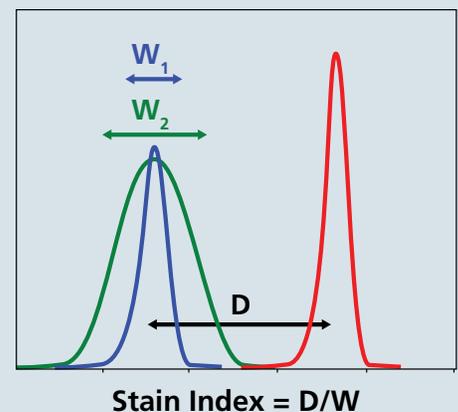

Stain Index = D/W

Figure 1. Resolution sensitivity (the ability to resolve a dim positive signal from background) depends upon the difference between positive and background peak means **(D)** and the spread of the background peak **(W)**. The stain index is a metric that captures both of these factors.

Selecting Reagents for Multicolor Flow Cytometry *(continued)*

Table 1. Stain index of various fluorochrome conjugates on a BD LSR II flow cytometer.

Reagent	Clone	Filter	Stain Index
PE	RPA-T4	585/40	356.3
Alexa Fluor® 647[1]	RPA-T4	660/20	313.1
APC[1]	RPA-T4	660/20	279.2
PE-Cy™7	RPA-T4	780/60	278.5
PE-Cy5[2]	RPA-T4	695/40	222.1
PerCP-Cy5.5[2]	Leu-3a	695/40	92.7
PE-Alexa Fluor® 610	RPA-T4	610/20	80.4
Alexa Fluor® 488[3]	RPA-T4	530/30	75.4
FITC[3]	RPA-T4	530/30	68.9
PerCP[2]	Leu-3a	695/40	64.4
APC-Cy7	RPA-T4	780/60	42.2
Alexa Fluor® 700	RPA-T4	720/45	39.9
Pacific Blue™	RPA-T4	440/40	22.5
AmCyan	RPA-T4	525/50	20.2

[1,2,3] Fluorochromes listed with the same superscript number are read in the same detector, and thus would not normally be used in combination.

When the same antibody is conjugated to various dyes, one can compare the stain index for those conjugates to get an idea of the relative brightness of the dyes on a particular instrument. This assumes, of course, that the conjugation chemistries for all of the reagents have been optimized. With this as a caveat, **Table 1** shows the stain index for a number of different CD4 conjugates, using the specified filters on a standard BD LSR II flow cytometer.

From this table, one can get an idea of the relative brightness of different fluorochromes on this platform. This leads to the first rule of reagent selection, which is to pick the brightest available fluorochromes. Suppose you have a 4-color panel consisting of reagents in FITC, PE, PerCP-Cy5.5, and APC, and you want to add a fifth color. PE-Cy7 is an obvious choice, since it is the brightest fluorochrome not already in your panel.

Minimize spillover

But brightness, on its own, only goes so far. The stain indexes listed in **Table 1** are calculated with the reagents run on their own, not as part of a cocktail. As soon as other reagents are added, spectral overlap (spillover) becomes an issue. Simply stated, the more colors one attempts to resolve, the more spillover between those colors that will have to be dealt with. We deal with spillover by applying compensation, which results in a correction being applied to all signals such that a cell population fluorescing only in PE, for example, will show no FITC fluorescence, on average. But while this is true for the population on average, individual cells will fall above or below the mean, and this data spread is higher when spectral overlap introduces additional noise.[1] Compensation, unfortunately, does not remove this noise. The effect of data spread is thus to reduce the resolution sensitivity, and therefore the stain index, for a

Table 2. Common choices for 6, 8, and 10-color experiments.

6-color	8-color	10-color
FITC or Alexa Fluor® 488	FITC or Alexa Fluor® 488	FITC or Alexa Fluor® 488
PE	PE	PE
–	–	PE-Texas Red® or PE-Alexa Fluor® 610
PerCP-Cy5.5	PerCP-Cy5.5	PerCP-Cy5.5
PE-Cy7	PE-Cy7	PE-Cy7
APC or Alexa Fluor® 647	APC or Alexa Fluor® 647	APC or Alexa Fluor® 647
–	–	Alexa Fluor® 680 or 700
APC-Cy7	APC-Cy7	APC-Cy7
–	AmCyan	AmCyan
–	Pacific Blue™	Pacific Blue™

fluorescence detector that receives spillover from other detector(s). As a result, we can state a second rule of reagent selection, which is to minimize the potential for spectral overlap when choosing a reagent combination. This can be in conflict with the first rule, which was to choose the brightest fluorochromes. For example, PE-Cy5 is very bright with regard to stain index **(Table 1)**, but it has considerable spillover into the APC detector. While these two fluorochromes can be used together, the resolution sensitivity in APC will be reduced compared to, for example, a combination of PerCP-Cy5.5 and APC. This is a case where one might wish to sacrifice a certain amount of brightness in one detector to avoid spillover (and loss of resolution sensitivity) in another.

Colors and specificities: Define winning combinations

Taking the two rules above into account, one can generalize a set of fluorochromes that are reasonable choices to use for experiments requiring 6, 8, or more colors **(Table 2)**. Note that these choices are based upon BD instruments (BD LSR II, BD FACSAria™ cell sorter, or BD FACSCanto™ flow cytometer), and upon reagents that can be generally purchased as catalog antibody conjugates.

Once the fluorochromes to be used have been defined, one can begin to match antibody specificities to particular fluorochromes. In other words, one can select the actual conjugates to be used. For this purpose, brightness and spillover remain key issues, as the following example illustrates.

Imagine that you want to look at CD62L staining on CD8[+] T cells. While CD8 is an abundant protein, and antibodies to it stain cells very brightly, CD62L is relatively dim (the protein is not abundant on the cell surface, and/or the available antibodies are of low affinity). Initially, one would be tempted to use the brightest available fluorochrome, PE, for CD62L, while using a dimmer fluorochrome, like FITC, for CD8. But FITC has considerable spillover into the PE
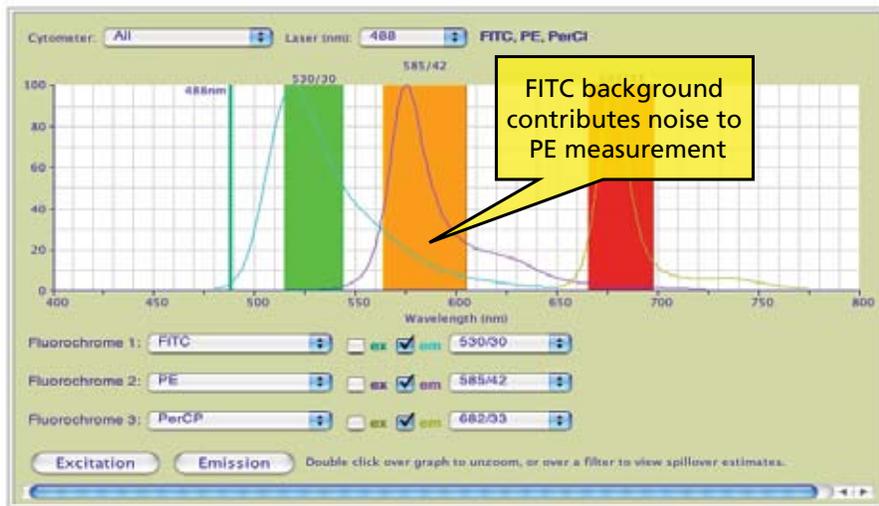

Figure 2. Spectral overlap of FITC into the PE detector. Taken from **bdbiosciences.com/spectra.**

detector (see **Figure 2**). The result is that, for CD8[+] cells that are highly stained in the FITC detector, resolution sensitivity in PE is compromised, to the point that CD62L resolution may be suboptimal. There are multiple possible solutions to improve this, including:

1. Moving CD8 to a detector that has less spectral overlap with PE (like PerCP-Cy5.5 or APC).

2. Moving CD62L to a detector that is still relatively bright, but does not overlap with FITC (like APC or PE-Cy5). Note that in this example, only the CD8[+] cells are highly stained in the FITC detector, so only CD8[+] cells contribute to data spread in the PE detector. If one were interested in CD62L staining only on CD4[+] (CD8[–]) cells, the original reagent combination (CD8 FITC, CD62L PE) would be fine.

This example illustrates two additional rules in reagent selection: Reserve the brightest fluorochromes for dim antibodies, and vice versa, but avoid spillover from bright cell populations into detectors requiring high sensitivity for those populations.

Tandem dyes: Watch out for degradation

One final topic to consider is the potential for tandem dye degradation. APC-Cy7, and to a lesser extent, PE-Cy7, can degrade in the presence of light, fixation, and elevated temperatures so that they emit in the parent dye detector (APC or PE). This process often starts with a small subpopulation of cells, leading to false positive events in APC or PE.[1] By minimizing the exposure of samples to light, heat, and formaldehyde-based fixatives, this problem can be largely avoided. Still, for some applications, it may be desirable to think about an additional rule: consider the consequences of degradation of tandem dyes and whether this will compromise sensitive readouts in the APC or PE detectors. If so, a different reagent configuration may be in order. For situations in which final fixation of samples is required (eg, biohazardous samples), there is a stabilizing fixative available that helps prevent degradation of APC-Cy7 while still fixing cells (BD Biosciences **Cat. No. 338036**).

Controls to validate your panel

Once all of these considerations have been taken into account, you are ready to test a multicolor reagent cocktail. In so doing, there are two types of controls that you may wish to include in your initial testing: fidelity controls and fluorescence-minus-one (FMO) controls.[2] Fidelity controls are those that use a given antibody by itself (or with minimal additional gating reagents), and compare the results to the use of that antibody in a complete cocktail. From this, one can see the effect of additional reagents on the readout of

interest, to be sure that the other reagents are not compromising that readout. FMO controls are those that combine all the reagents in a given cocktail, except for one reagent of interest. These are useful to gauge the sensitivity of particular detectors in the context of the other reagents. They may also be used for routine gating of those detectors for which other means of setting gates are not possible or practical. In general, though, once a reagent panel has been well validated, it is not necessary to run all of these controls on a day-to-day basis.

To summarize, this article has set forth rules for selecting reagents for multicolor flow cytometry. These rules, although sometimes in conflict with each other, need to be balanced to achieve the best possible results:

Rule 1: Choose the brightest set of fluorochromes for your particular instrument configuration.

Rule 2: Choose fluorochromes so as to minimize the potential for spectral overlap.

Rule 3: Reserve the brightest fluorochromes for dim antibodies, and vice versa.

Rule 4: Avoid spillover from bright cell populations into detectors requiring high sensitivity for those populations.

Rule 5: Take steps to avoid tandem dye degradation, and consider its impact on the results.

With time, proven panels of multicolor reagents will become available, both in the literature and from manufacturers, such that many users will not have to start from scratch in designing reagent panels. Nevertheless, given the huge variety of applications of multicolor flow cytometry, most researchers will at least sometimes find themselves having to select their own multicolor reagents, we hope that these rules will prove helpful.

Fluorochromes for combinations beyond the typical 5-color experiment

Multicolor Flow Cytometry Reagents

Expand your multicolor flow with options beyond the typical 5 colors

- BD Biosciences continues to increase our portfolio of multi-color reagents to support your cutting-edge research using the expanded fluorescence detection capabilities of our flow cytometers.

- We offer directly conjugated antibodies to fluorochromes that go beyond your typical 5 colors by providing colors off the violet, red, and blue lasers. These include AmCyan, Pacific Blue™, Alexa Fluor® 700, and PE-Cy7 conjugates to support up to 9-color staining with off-the-shelf reagents. See **page 5** for details.

- BD Biosciences Custom Conjugation Program* offers even more choices for your multicolor experiment design. This program offers multiple colors, as shown in the table below.

Custom conjugates available from BD Biosciences

| Fluorochrome	Ex Max (nm)
Alexa Fluor® 405	401
Alexa Fluor® 488	495
